

# Laboratory 4: Image Mosaicing (Including Final Projects Intro)

Computer Vision 2022

# CV 2022: HW / Projects

1. Introduction to C++ / OpenCV

No HW

2. Histogram and Filtering

3. Road Line Detection

- Select 1 among 2 and 3
- First «simple» HW: 3 pts
- Provide a very short report or comments in the source
- On/off mark

4. Image Mosaicing

5. Parking Spaces Det.

- Select 1 among 4 and 5
- Second «advanced» HW: 6 points
- More detailed report with results
- Mark based on solution quality

Final Exam (written in classroom): ~23 points

Final mark: 3 + 6 + 23 = max 32 points

## Two options:

1. *Image mosaicing with feature descriptors (LAB4)*
2. Detection of free parking spaces (*LAB5*)

# Project 1: Image Mosaicing

- Join multiple images to create a single bigger image
- *Stitching*: process of joining the various images together
- The task can be performed by finding feature points and matching them across the images

# Merge 3x3 Tiles into Mosaic

# Algorithm to be Developed

1. Load a set of 9 images roughly arranged in a 3x3 grid
  - ☐ You can use one of the provided sets
  - ☐ They have been obtained by splitting a larger image and applying some transformations
  - ☐ Letters underline the applied transforms (TTranslation, SScaling, RRotation, NNoise, LLight changes)
  - ☐ Different sets have different level of complexity, no need to solve all of them
2. Extract ORB or SIFT features from the images (SIFT features requires OpenCV>4.4)
3. For each couple of images
  - ☐ Compute the match between the different features extracted in step 2
  - ☐ You can use the `cv::BFMatcher` class (use L2 for SIFT and Hamming distance for ORB)
  - ☐ Refine the found matches by selecting the matches with distance less than  $ratio * min\_distance$ , where  $ratio$  is a user-defined threshold and  $min\_distance$  is the minimum distance found among the matches
4. You can assume the images are linked together by an affine transform
  - ☐ Using the refined matches find the transformation between the images
  - ☐ You can use the RANSAC algorithm implemented into the CV `findHomography()` function

*This is the baseline assignment, see the next slide for additional suggestions for extra features improving your mark*

# Extra Ideas

1. Manually implement RANSAC and affine transform estimation
2. Try other algorithms/strategies
3. Try also panoramic images besides the mosaic
4. Acquire your own images (you can take 9 images moving the camera or acquire a single image, split in 9 and try to recombine)
5. Work with color images instead of grayscale
6. Try different feature descriptors
7. Use some blending/mixing techniques for better results
8. Equalize the images to avoid color jumps (test on the “L” images)
9. Try to automatically guess which images are linked to which

*Differently from HW1, this final project lab has a mark, a few of these or any other «extra» idea could improve your mark*

# OpenCV: Feature 2D Class

```
virtual void  
cv::Feature2D::  
detectAndCompute  
    ( InputArray          image,          Input image  
  
      InputArray          mask,           Compute KP only in regions  
                                           where mask is not 0  
  
      std::vector< KeyPoint > & keypoints, Output keypoints (location,  
                                           orientation, scale)  
  
      OutputArray         descriptors,     KP descriptors  
  
      bool                useProvidedKeypoints Set to false  
                               = false  
    )
```

- Base class for feature extractor and descriptors
- *detect* (feature extraction), *compute* (feature description) and *detectAndCompute* (both stages) methods
- Constructor depends on the employed subclass

# SIFT in OpenCV

<pre> static <u>Ptr</u>&lt;<u>SIFT</u>&gt; cv::SIFT::create       ( int      nfeatures = 0,         int      nOctaveLayers = 3,         double   contrastThreshold = 0.04,         double   edgeThreshold = 10,         double   sigma = 1.6       ) </pre>	<p># of feature points to extract</p> <p># of layers in each octave</p> <p>Threshold on <math>D(\hat{x})</math></p> <p>Threshold on eigenvalue ratio</p> <p>Smoothing of the 1st img 1st octave</p>
---	---

*Usually better performances than ORB*

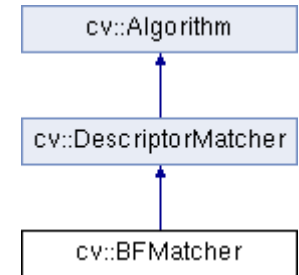

# ORB in OpenCV

<code>static <a href="#">Ptr&lt;ORB&gt;</a></code>	<code>( int nfeatures = 500,</code>	Max # of features to extract
<code>cv::ORB::create</code>	<code>float scaleFactor = 1.2f,</code>	Scale step between different pyramid levels
	<code>int nlevels = 8,</code>	# of pyramid levels (multi-scale)
	<code>int edgeThreshold = 31,</code>	Avoid computing features close to image boundaries
	<code>int firstLevel = 0,</code>	Set to 0
	<code>int WTA_K = 2,</code>	Set to 2 for comparison between couples of points as in the theory
	<code>int scoreType = <a href="#">ORB::HARRIS_SCORE</a>,</code>	Rank extracted corners with Harris criteria
	<code>int patchSize = 31,</code>	Size of patch for feature computation
	<code>int fastThreshold = 20</code>	Threshold in FAST algorithm
	<code>)</code>	

# Feature Matching

```
static Ptr<BFMatcher>
cv::BFMatcher::create ( int      normType = NORM_L2,
                        bool      crossCheck = false
                      )
```

- ☐ Brute-Force matching
- ☐ Select the type of distance function
  - ☐ Use ***NORM\_L2*** for SIFT and ***NORM\_HAMMING*** for ORB
- ☐ ***crossCheck*** : if *true* forces that if A matches B then B must match A

# cv::findHomography

<u>Mat</u>	cv::findHomography	(	<u>InputArray</u>	srcPoints,	Coordinates of the points in the 1 <sup>st</sup> image, a matrix of type CV_32FC2 or a vector<Point2f>
			<u>InputArray</u>	dstPoints,	Coordinates in the 2 <sup>o</sup> image
			<u>OutputArray</u>	mask = <u>noArray</u> (),	Not needed
			int	method = 0,	Use cv::RANSAC
			double	ransacReprojThresh = 3,	Threshold on reprojection error for a point to be considered an inlier
				)	

- ❑ Finds the homography between object and its location in the image
- ❑ Returns 3x3 matrix with the computed homography

$$s_i \begin{bmatrix} x'_i \\ y'_i \\ 1 \end{bmatrix} \sim H \begin{bmatrix} x_i \\ y_i \\ 1 \end{bmatrix}$$

# Estimate the Affine Transform

coord. on image

coord. on object

$$\begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} m_1 & m_2 \\ m_3 & m_4 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} t_x \\ t_y \end{bmatrix}$$

$$\begin{bmatrix} x_1 & y_1 & 0 & 0 & 1 & 0 \\ 0 & 0 & x_1 & y_1 & 0 & 1 \\ x_2 & y_2 & 0 & 0 & 1 & 0 \\ 0 & 0 & x_2 & y_2 & 0 & 1 \\ x_3 & y_3 & 0 & 0 & 1 & 0 \\ 0 & 0 & x_3 & y_3 & 0 & 1 \end{bmatrix} \begin{bmatrix} m_1 \\ m_2 \\ m_3 \\ m_4 \\ t_x \\ t_y \end{bmatrix} = \begin{bmatrix} u_1 \\ v_1 \\ u_2 \\ v_2 \\ u_3 \\ v_3 \end{bmatrix}$$

$$Ax = b$$

$$\min_x (\|Ax - b\|^2)$$

- *Use the OpenCV `findHomography()` function*
  - *Estimates a more general transformation than the affine one*
  - *8 parameters (DoF) instead of 6*
  - *Includes the RANSAC algorithm*
- *Otherwise (advanced, optional) implement manually a simplified RANSAC estimator*
  1. Try different random sets of 3 points
  2. For each set of **3 KP** estimate the corresponding affine transform
  3. Find the one with the largest consensus set
- *Simpler (but slower) than the Hough Transform approach seen in the theory, but enough for simple cases*

# RANSAC (*simplified*)

1. Select a random set of 3 correspondences
2. Estimate the affine transform
3. Count how many correspondences are consistent with the selected one. The criteria can be a threshold on the difference between the projections of the keypoint and their locations,  
 $|\Delta u_{max}| + |\Delta v_{max}| < T$  (e.g.,  $T=3$ )
4. Iterate  $n$  times (e.g.,  $n=100$ ) and keep the correspondence with the largest compatible set

*Included inside openCV findHomography()*

# Panoramic Images

- Pictures covering a  $360^\circ$  field of view in the horizontal direction
- Panoramic images can be built from a set of pictures taken with a rotating camera from a single viewpoint

# Cylindrical Projection

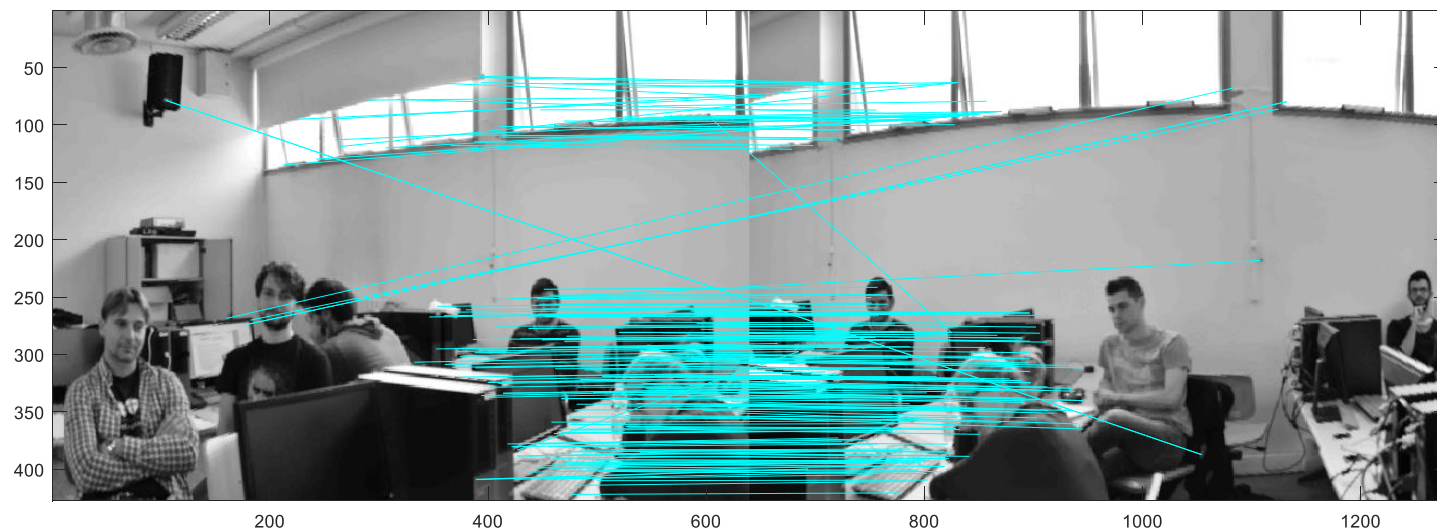

- The photos are projected on a cylinder
- After the cylindrical mapping the transformation between the various pictures becomes a simple *translation*
- See the file '[cylindrical\\_projection.pdf](#)' for the theory and equations of the projection
- The code for this task is already provided in the "[panoramic\\_utils.h](#)" and "[panoramic\\_utils.cpp](#)" files

# Example (Cylindrical Projection)

# Example (Matching)

# Examples (Panoramic Image)

*Matlab+Lowe's toolbox*

*c++ - OpenCV - SIFT*

*c++ - OpenCV - ORB*

# Project 2: Parking Slot Detector

- Find free parking slots in the provided images
- A training set and a test set are provided to allow you to use machine learning approaches
- *More details later during the course*

# Parking Slot Detector

Have a look at this two datasets

- <https://web.inf.ufpr.br/vri/databases/parking-lot-database/>
- <http://cnrpark.it/>

More detail later in the course, general ideas:

1. Download the data and extract the information you need for the task
2. The datasets are divided into train and test sets
  - ☐ The training set is needed only if you use ML-based approaches
3. *Task*: find which parking slots are free and which are occupied
4. Possible approaches:
  - ☐ Run edge/corner/feature detector into the slot and analyse found features
  - ☐ Analyse image statistics into the slot
  - ☐ Extract features (e.g. SIFT, ORB) , then use ML classifiers, e.g., SVM or Random Forests
  - ☐ Deep learning CNN binary classifier
  - ☐ Deep learning object detector

# Support for the Final Project

*Come to the labs, ask at the end of the lecture or contact by email the teaching assistant assigned to you*

Surname	Teaching Assistant	email
